㉔ Novel human interleukin 4, expression vectors for human interleukin 4 and transformants
containing the same.

㉗ The present invention provides novel human interleukin 4 (IL4) having immune-activating effects, which is characterized by (a) a total molecular weight of 17000 to 19000, and (b) a sugar chain molecular weight of 2000 to 4000; and also provides novel expression vectors for the human IL4 which comprises: (i) a DNA sequence encoding human interleukin 4 at a position downstream from an SV40 early promoter, and (ii) a DNA sequence encoding dihydrofolate reductase at a position downstream from a promoter operating in eukaryotic cells; and further provides transformants obtained by transfecting dihydrofolate reductase-defective Chinese hamster ovary cells with the expression vector for human IL4. The human IL4 is useful for the treatment and prevention of cancer, infections, AIDS, functional immune deficiency etc.

NOVEL HUMAN INTERLEUKIN 4, EXPRESSION VECTORS FOR HUMAN INTERLEUKIN 4 AND TRANSFOR- MANTS CONTAINING THE SAME

FIELD OF THE INVENTION

5   The present invention relates to novel human IL4 having immune-activating effects, novel expression vectors for said human IL4 and novel transformants thereof.

BACKGROUND OF THE INVENTION

10

Interleukin 4 (hereafter "IL4") is a glycoprotein produced by T lymphocytes when stimulated with lectin, phorbol ester or antigen. IL4 has various significant effects on the immune response, such as differentiation and proliferation, of B lymphocytes, of T lymphocytes and of mast cells (see Y. Noma et al., Nature, 319, 15   640-646, 1986 (hereafter "Reference A"); F. Lee et al., Proc. Natl. Acad. Sci. USA, 83, 2061-2065, 1986 (hereafter "Reference B"); E. Severinson et al., Eur. J. Immunol., 17, 67-72, 1987 and T. R. Mosmann et al., Proc. Natl. Acad. Sci. USA, 83, 5654-5658, 1986). Since IL4 has such strong immune-activating effects, it is believed that IL4 is useful for the prevention and treatment of infections, AIDS, cancer, immune deficiency, etc. (see R. Fernandez-Botran et al., Proc. Natl. Acad. Sci. USA, 83, 9689-9693, 1986 and R. Palacios et al., 20   EMBO J., 6, 91-95, 1987).

Native human IL4 can be obtained by treating normal human peripheral blood lymphocytes, malignant human T cell lines or human T cell hybridoma with drugs. However, since only a very small amount of IL4 is produced by these methods, physical and chemical characteristics (e.g. the total molecular weight, molecular weight of the sugar chain, the isoelectric point, etc.) of human IL4 per se have not yet been 25   determined. Further, it has been impossible to obtain a sufficant amount of purified human IL4 for clinical use. Hence, it has been desired to develop a method for preparing large amounts of IL4 by utilizing genetic engineering techniques.

In recent years, the cDNA of mouse IL4 has been cloned (see Reference A and Reference B). Further the cDNA of human IL4 has been cloned by using the mouse DNA as probe (see T. Yokota et al., Proc. 30   Natl. Acad. Sci. USA, 83, 5894-5898, 1986 (hereafter "Reference C")). The nucleotide sequence thereof and the expression of human IL4 by culturing monkey cells transfected with the human cDNA, have been reported (see Reference C and PCT Patent International publication No. WO 87/02990). Further, a yeast expression system for producing human IL4 has been reported (see J. Exp. Med., 166, 476, 1987). However, IL4 is expressed in monkey cells transiently, and the cells die after producing human IL4. Thus, 35   the cells used are not available for expression again, and it is necessary to always transfect fresh cells. Moreover, a number of DNA vector and a good deal of work are required for transfection. Thus, the method using monkey cells is not suitable for supplying enough human IL4 for clinical use. To date, there has been no report of an effective expression system for human IL4.

In order to obtain foreign gene products utilizing genetic engineering techniques, many expression 40   vectors and hosts for expressing the vector (for example, procaryotic cells such as Escherichia coli, Bacillus subtilis, Actinomycetes, Lactobacillus, etc. and eucaryotic cells, such as yeast, fungi, mammalian cells, etc.) have ever been found. Recently, it has been observed that it is necessary to select an expression vector and a host most suitable for the gene in order to obtain a particular gene product, especially with high efficiency as used in commercial production.

45

SUMMARY OF THE INVENTION

50   Accordingly, an object of the present invention is to provide large quantities of human IL4 useful for the prevention and treatment of infections, AIDS, cancer, immunodeficiency, etc.

Another object of the present invention is to provide an expression vector for the production of large quantities of human IL4.

Still another object of the present invention is to provide transformants which express large quantities of

human IL4.

The above-described objects of the present invention have been met by a novel human IL4 having specific physical and chemical characteristics produced by utilizing an expression vector which comprises a DNA sequence encoding human IL4 at a position downstream from an SV40 early promoter, and a DNA sequence encoding dihidrofolate reductase (hereafter "DHFR") at a position downstream from the promoter, and by utilizing dihydrofolate reductase- defective Chinese hamster ovary cells (hereafter "CHO cells"), as host cells.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 shows the nucleotide sequence of the cDNA of human IL4 and the amino acid sequence deduced therefrom.

Figure 2 shows construction of the pKCRhIL4-Dn expression vector for human IL4.

Figure 3 shows construction of the pKCRhIL4Δ-D expression vector for human IL4.

Figure 4 is a densitometer graph obtained after separating human IL4 by SDS/PAGE.

DETAILED DESCRIPTION OF THE INVENTION

As a result of continuous research on an IL4 expression system using a mammalian cells as host, an expression system with high efficiency has been found in the present invention comprising the combination of an expression vector containing SV40 early promoter and CHO cells. It has also been found in the present invention that by incorporating the gene of DHFR in the expression vector and further by using DHFR-defective cells, an expression system with more high efficiency can be obtained.

Furthermore, it has been confirmed that novel human IL4 produced by the expression system of the present invention has specific physical and chemical characteristics (e.g. molecular weight of the sugar chain, etc.).

Although an expression system using CHO cells as host has been already applied to the expression of some biological active proteins, each protein has quite different sugar chain, length of the chain, sugar components, etc. These differences are represented by the molecular weight of the sugar chain, etc, as shown in Table I below.

Table I

Proteins	molecular weight of sugar chain (Kd)
Interferon-γ[1]	5
Erythropoietin[2]	15
Tissue plasminogen activator (t-PA)[3]	10

1) Roger Dijkmans et al., J. Biol. Chem., 262, 2528-2535, 1987
2) Fu-Kuen Lin et al., Proc. Natl. Acad. Sci. USA, 82, 7580-7584, 1985
3) Randal J. Kaufman et al., Molecular and Cellular Biology, 5, 1750-1759, 1985

Accordingly, it can not be said that glycoproteins having sugar chains with the same characteristics are produced, when the expression system using CHO cells is applied to the expression of various glycoproteins.

The present invention provides in particular:

(1) novel human IL4 characterized in that:

(a) the total molecular weight is 17000 to 19000, and

(b) the molecular weight of the sugar chain is 2000 to 4000:

(2) a novel expression vector for human IL-4 which comprises:

3

(i) a DNA sequence encoding human IL4 at a position downstream from an SV40 early promoter, and

(ii) a DNA sequence encoding DHFR at a position downstream from a promoter operating in eukaryotic cells;

(3) a novel transformant which is obtained by transfecting DHFR-defective CHO cells with the vector of (2); and

(4) a novel human IL4 which is produced by using the transformant of (3) as the host.

In human IL4, the amino acid sequence of the protein moiety thereof is shown by the following formula:

MetGlyLeuThrSerGlnLeuLeuProProLeuPhePheLeu
LeuAlaCysAlaGlyAsnPheValHisGlyHisLysCysAsp
IleThrLeuGlnGluIleIleLysThrLeuAsnSerLeuThr
GluGlnLysThrLeuCysThrGluLeuThrValThrAspIle
PheAlaAlaSerLysAsnThrThrGluLysGluThrPheCys
ArgAlaAlaThrValLeuArgGlnPheTyrSerHisHisGlu
LysAspThrArgCysLeuGlyAlaThrAlaGlnGlnPheHis
ArgHisLysGlnLeuIleArgPheLeuLysArgLeuAspArg
AsnLeuTrpGlyLeuAlaGlyLeuAsnSerCysProValLys
GluAlaAsnGlnSerThrLeuGluAsnPheLeuGluArgLeu
LysThrIleMetArgGluLysTyrSerLysCysSerSer

(see Reference C).

It has been confirmed that the human IL4 of the present invention contains 129 amino acids from the 25th amino acid, histidine to the 153rd amino acid, serine, and lacks amino acids from the first amino acid, methionine to the 24th amino acid, glycine (see Examples 8 and 9 described hereinafter).

The sugar chain of the human IL4 of the present invention is quite distinct from that of the human IL4 known to date.

The molecular weight of the human IL4 of the present invention is 17 to 19 kd (kilodaltons). The molecular weight of only the protein moiety is 14962. Therefore, the difference in molecular weight between total human IL4 and the protein moiety, i.e. 2000 to 4000, preferably 2500 to 3500, is considered to be the molecular weight of the sugar chain.

On the other hand, the molecular weight of human IL4 expressed by monkey cells, described in PCT Patent International Publication No. WO 87/02990 is 22 kd, and hence that of the sugar chain is considered to be about 7 kd. Therefore, it is confirmed that the quantity of the sugar chain bonded to the protein moiety in the human IL4 expressed by monkey cells is more than two times that in the human IL4 of the present invention. In addition, there is a great difference in molecular weight between the sugar chains of both human IL4s.

Furthermore, the molecular weight of human IL4 expressed by yeast is 60 kd and that of the sugar chain is considered to be 45 kd. Hence, the molecular weight of the sugar chain of the human IL4 expressed by yeast is greatly different from that of the present invention.

The human IL4 of the present invention preferably has a isoelectric point of 8.5 to 10.5, more preferably 9.8 to 10.1.

More preferably, the human IL4 of the present invention has a sugar chain which comprises at least mannose, fucose and galactose as neutral sugars, at least glucosamine as an amino sugar and at least N-acetylneuraminic acid as a sialic acid.

Further, the human IL4 of the present invention preferably has a sugar chain wherein mannose, fucose, galactose, glucosamine and N-acetylneuraminic acid are contained in amounts of 3.0 to 4.0, 1.0 to 2.0, 2.5 to 3.5, 4.5 to 5.5 and 1.5 to 2.5, mols per total mol of sugar, respectively.

The human IL4 of the present invention is sufficiently pure, but is not necessarily a single chemical compound. The present invention may comprise many homogenous human IL4 having various characteristics within the scope described above and heterogeneous human IL4 having slightly different sugar chains.

The present invention also includes the expression vector for human IL4 and the transformant.

The expression vector for human IL4, of the present invention may be prepared by ligating:

(iii) a DNA sequence containing an origin of replication and drug resistance gene in Escherichia coli, besides the DNA sequences of (i) and (ii) mentioned above.

The DNA of human IL4 may be prepared by (1) extracting mRNA from cells being capable of producing IL4, such as normal human lymphycytes, (2) constructing cDNA by using reverse transcriptase, and, then, (3) cloning the cDNA from the obtained cDNA library in Escherichia coli. For example, the desired cDNA may be selected from a cDNA library by cross-hybridization using a part of the cDNA of mouse IL4 (described in Reference A and B) as a probe or by using the biological activities of human IL4 as a screen.

4

Efficient selection is a obtained by using both of the above methods together. It is also possible to select by hybridization using a synthetic oligonucleotide having a partial nucleotide sequence of cDNA of human IL4, which has already reported (described in Reference C), as probe.

Recently, it has been reported that a nucleotide sequence rich in adenine (A) and uracil (U) exists in a
5 non-translated region at the 3'-side of mRNA of lymphokines such as IL4 and that this sequence relates to the instability of mRNA itself (see G. Shaw et al., Cell, 46, 659-667, 1986). It is considered by the present inventors that in IL4, three groups of the nucleotide sequence shown by "ATTTA" (i.e.; from 472nd to 476th, from 506th to 510th and from 514th to 518th), correspond to that relating to instability. Therefore, if the desired products are considered to be produced more efficiently, host cells are transfected with an IL4
10 vector wherein the nucleotide sequence for instability has been removed. As a result of a study based on these hypotheses, it has been found in the present invention that by removing the entire nucleotide sequence existing in the position downstream from the nucleotide sequence signaling for the termination of translation of human IL4 (i.e., the nucleotide sequence downstream adenine, the 464th), human IL4 is produced several ten times more, as compared with the use of a vector wherein this sequence is not
15 removed. It is the present inventors who have first confirmed such fact by experiments. Of course, the production of IL4 is considered to increase similarly by removing only three groups of the nucleotide sequence for instability.

The.DNA of human IL4 wherein the nucleotide sequence for instability is removed may be prepared by (1) cleaving the vector DNA containing the cDNA of human IL4 by a restriction enzyme which recognizes a
20 particular nucleotide sequence existing singly at a position downstream from the nucleotide sequence for instability, e.g. Sal I, (2) digesting with a nuclease such as Bal 31, and ,then, (3) cloning the obtained DNA fragment into Escherichia coli.

By using either the DNA wherein at least the nucleotide sequence for instability is or is not removed, the purpose of the present invention may be accomplished. The expression "the DNA where at least the
25 nucleotide sequence for instability is removed" means that three groups of nucleotide sequences shown by "ATTTA" in the 3' non-translated region of the DNA are removed alone or along with some or all of the remaining 3' non-translated region. However, it is preferable to use the DNA wherein at least the nucleotide sequence for instability is removed.

As vectors for expressing human IL4 in a mammalian cell, any vectors containing an SV40 early
30 promoter may be used. Examples of such vectors are pSV2 vector (see R. C. Mulligan et al., Science, 209, 1422-1427, 1980) and pKCR•H₂ vector (see K. O'Hare et al., Proc. Natl. Acad. Sci., USA, 78, 1527-1531, 1981). pKCR•H₂ vector is preferred.

pKCR•H₂ vector has a splicing sequence and polyadenylation sequence, both derived from the gene of β-globin, besides an SV40 early promoter. Therefore, it is suitable for the expression of the desired product
35 in mammalian cells. Furthermore, this vector has an origin of replication in Escherichia coli and an ampicillin resistance gene as a selection marker, ·in order to enable the replication in Escherichia coli. Hence, pure vector DNA may be prepared in quantity by using Escherichia Coli.

The DHFR gene may be prepared by the method known (see R. J. Kaufman et al., Molecular and Cellular Biology, 2, 1304-1319, 1982). As promoters for the expression of the DHFR gene, any promoters
40 operating in eukaryotic cells, such as an SV40 early promoter, metallothionein gene promoter, adenovirus gene promoter, retrovirus gene promoter etc. may be used.

By combining three DNA sequences having above-mentioned features, the expression vector for human IL4 may be prepared, and the preparation may be carried out by conventional methods well-known to those skilled in the art (see T. Maniatis et al., Molecular Cloning, Cold Spring Harbor Laboratory, 1982).
45 Dihydrofolate reductase-defective Chinese hamster ovary cells (hereafter "CHO dhfr- cells") for the transfection of the expression vector for human IL4 are described in G. Urlaub et al., Proc. Natl. Acad. Sci. USA, 77, 4216-4220, 1980. The transfection of the vector DNA into CHO dhfr- cells may be carried out by methods known, for example, by the calcium phosphate method (described in F. L. Graham et al., Virology, 54, 536-539, 1973).
50 The above cells of the present invention, in which the expression vector was transfected, may be selected by utilizing the property that the transformant can grow even in a culture medium for selection in which the parent CHO dhfr- cells die for lack of thymidine and hypoxanthine.

The transformant in which the DHFR gene is amplified by the action of an antagonistic inhibitory agent for DHFR may be easily distinguished from that in which DHFR gene is not amplified, because the former
55 can grow in a culture medium containing an antagonistic inhibitory agent for DHFR, e.g. methotrexate.

One of the transformants of the present invention obtained in this way, which was named CHO-B91 cells, has been deposited at the Institute for Fermentation, Osaka, Japan (IFO) with deposit No. IFO 50137 and deposited at the Fermentation Research Institute, Ibaraki, Japan (FRI) with deposit No. BP-1752.

The transformant of the present invention, which produces human IL4 efficiently and in quantity, may be cultured in a conventional culture medium (for example, α-MEM containing 10%(v/v) fetal bovine serum) in the presence or absence of methotrexate. The desired protein, secreted into the culture medium, may be purified by conventional methods, for example salting-out techniques, ion-exchange chromatograpy, gel-filtration methods, hydrophobic column chromatograpy, affinity chromatograpy, etc.

The human IL4 obtained by the present invention improves the immune response and hence is useful for the treatment and prevention of diseases which require such improvement, for example cancer, infections, AIDS, functional immune deficiency, etc. The suitable dose may vary with the conditions of disease, age, sex and body weight, of the subject. For example, a suitable dosage is between 0.1 μg to 1 mg for intravenous administration.

The stimulatory activity on human lymphocyte growth was used as an indication of immune-activating effects of human IL4 in the present invention. The stimulatory activity on human lymphocyte growth was measured by the following method.

Lymphocytes prepared from human peripheral blood were suspended in the culture medium (RPMI-1640 containing 10%(v/v) fetal bovine serum and 5×10^{-5} M 2-mercaptoethanol) containing phytohemag-glutinin (10 μg/ml), and cultured for 4 to 6 days at 37°C in the presence of 5% CO_2. The cultured lymphocytes were washed with the culture medium (more than three times), and 5×10^4 lymphocytes thus obtained were again suspended in 200 μl of the culture medium. After adding a test sample therein, the suspension was further cultured for three days. It was pulsed with tritium labeled thymidine (0.25 μCi/culture) for 12 hours before termination of culturing. Then, the incorporation of thymidine into the high molecular fraction were measured by a liquid scintillation counter. The relative activity measured was 2.5 – 10×10^5 U/mg of protein.

Furthermore, antibody against human IL4 may be prepared by using human IL4 of the present invention as an antigen, and receptors of human IL4 can be isolated and purified by using the human IL4 as a ligand.

The following Examples illustrate the present invention in detail, but are in no way intended to limit the scope of the preent invention.

Example 1

Preparation of human IL4 cDNA

(i) Separation of mRNA for human IL4

Human peripheral blood lymphocytes were suspended in RPMI 1640 medium supplemented with 10%-(v/v) fetal bovine serum (hereafter "FBS"), 5×10^{-5} M of 2-mercaptoethanol and 1 μg/ml of phorbol-12-mylistate-13-acetate (hereafter "PMA"), and then incubated at 37°C in 5% CO_2 for 12 hrs.

The cultured lymphocytes were washed with RPMI 1640 supplemented with 10%(v/v) FBS twice to remove PMA and resuspended in the same medium which contained 3 μg/ml of Concanavalin A (hereafter "Con-A") to induce IL-4. After 6 hrs induction, RNA was extracted from 6×10^9 of these lymphocytes using the guanidiumthiocyanate method (see Chivgwin, J.M., Przybyla, A.E., MacDonald, R.J. and Ruttev, W.J., Biochemistry, 18, 5294, 1979) and subsequently purified with an oligo(dT) cellulose column to yield 89 μg of mRNA containing poly A fraction.

An aliquot of mRNA obtained above was micro-injected into Xenopus laevis oocytes, which were incubated in modified Barth's medium (Colman, A., Transcription and Translation - a practical approach, pp 291; edited by Hames, B.D. and Higgins, S.J.; IRL Press 1984) at 20°C for 36 hr.

The biological activity for human IL4 produced threrein was examined by the activation human peripheral blood lymphocytes and human tonsilar B-lymphocytes as follows: human peripheral blood lymphocytes were cultured in RPMI-1640 supplemented with 10%(v/v) FBS, 5×10^{-5} M of 2-mercaptoethanol and 10 μg/ml of phytohemagglutinin, at 37°C in 5% CO_2 for four to six days. These lymphocytes were washed (over three times) with medium and 5×10^4 cells were resuspended into 200 μl of medium which contained the sample to be examined. The incubation was continued for additional three days. During the final 12 hrs, the cells were pulse-labeled with [^{3}H]-thymidine (0.25 μCi/culture) to measure the

incorporation of the radioactivity into a high molecular weight fraction of the cells. Also, human lymphocytes prepared from human tonsils were purified using the rosetta formation using 2-aminoethylisothiouronium bromide treated sheep red blood cells (SRBC) to remove T lymphocytes. The purified B-lymphocytes obtained were incubated in RPMI-1640 supplemented with 10%(v/v) FBS, 5×10^{-5} M of 2-mercaptoethanol

5 and 5 µg/ml of anti-IgM antibody bound glass beads, at 37°C in 5% CO_2 for two to three days. Anti-IgM antibody bound beads were removed by density gradient centrifugation using lymphoprep (trade name, product of Nyegaard Inc.). B-lymphocytes were washed with the medium and then 5×10^4 cells were resuspended in 200 µl of medium each. Sample supernatants were added into this cell suspension and the mixture was allowed to incubate for the additional two days. The activity was measued by [³H]-thymidine

10 incorporation as described above.

(ii) Preparation of cDNA library

15   The cloning plasmid pCDV₁-PL (described in Reference A) was digested with the restriction enzyme Kpnl. To the 3′-ends of this fragment, an oligo dT chain, average of 45 bases, was added with terminal deoxynucleotidyl transferase. This fragment was digested with EcoRI and the larger fragment was recovered from an agarose gel. Upon passing the larger fragment through an oligo (dA) column, the purified vector-primer was obtained.

20   Then, Plasmid pSP62-K2 (described in Reference A) was digested with SacI. To the 3′-ends of this fragment, an oligo dG chain, average of 14 bases, was added with terminal deoxynucleotidyl transferase. This fragment was digested with HindIII to obtain the linker DNA as the smaller fragment.

Using six µg of polyA⁺ RNA described in Example 1(i), a cDNA was synthesized with 2 µg of vector primer as a template with 10 units of reverse-transcriptase. To the 3′-ends of the cDNA, an oligo dC chain,

25 average of 14 bases, was added with terminal transferase. After the primer was digested with HindIII, the cDNA fragment was ligated with the linker. The first strand, RNA, was made into DNA with E. Coli polymerase I and R Nase H. E. Coli HB101 was transformed with the plasmid thus obtained to prepare a cDNA library which contained about one million independent clones.

30

(iii) Preparation of probe

Plasmid pSP6 KmIL4-374 (described in Reference A), which carried mouse IL4 cDNA, was digested with BamHI to excise an about 800 base pair insert. This fragment was further digested with Bal 31 in 40 µl

35 of reaction mixture which contained 35 µg of DNA, 12 mM of $CaCl_2$, 12 mM of $MgCl_2$, 0.2 M of NaCl, 20 mM of Tris-HCl buffer (pH 8.0), 1 mM of EDTA and 0.3 units of Bal 31, at 30°C for 3 min. After the mixture was extracted the phenol, DNA was precipitated with ethanol, and then a BamHI linker was ligated with T4-ligase. The BamHI treated DNA fragment was inserted in the BamHI site of pUC 18 to prepare a plasmid pSP6mIL4Δ. The 5′-fragment obtained with BamHI/Rsal digestion does not contain any part of SP6 vector.

40 At the same time, the Rsal/Rsal fragment was prepared, which covered most of the protein coding region.

(iv) Selection of cDNA clone

45   The cDNA library described above was adhered to GSN filters (product of German Science Inc.) to prepare four replica filters. Two fragments prepared from mouse IL4 cDNA, BamHI/Rsal (120 bp) and Rsal/Rsal (373 bp) were nick-translated independently to yield highly labeled probes (about 5×10^8 cpm/µg). Two replica filters were hybridized with each probe independently (50mM Tris-HCl buffer (pH 7.8), 10 mM EDTA, 1M NaCl, 0.1%(w/v) BSA, 0.1%(w/v) polyvinylpyrrolidone, 0.1%(w/v) Ficol 400, 0.1%(w/v)

50 SDS and 50 µg/ml of sonicated salmon sperm DNA) at 37°C for 24hrs. All of the filters were washed in 6×SSC (1×SSC: 0.15 M NaCl and 0.015M sodium citrate) and 0.1%(w/v) SDS at ambient temperature for 1 hr three times and then in 2×SSC, 0.1%w/v) SDS at 37°C for 20 min twice. One filter in each case was further washed in 2×SSC, 0.1%(w/v) SDS at 42°C for 20 min. After autoradiography at -80°C, 258 and 68 clones showing a relatively strong signal compared with the background were selected from BamHI/Rsal

55 and Rsal/Rsal hybridization, respectively. About ten colonies around one signal were picked and suspended in 100 µl of L-broth. Then the independent ten pools were combined to one pool to yield 26 and 7 pools from BamHI/Rsal and Rsal/Rsal hybridization, respectively. Plasmid DNA obtained from each pool was digested with SalI and the thus obtained templates were used to prepare 1.5 ~ 2.5 µg of mRNA with SP6

RNA polymerase. After phenol/chloroform treatment and ethanol precipitation, mRNA was dissolved in PBS to prepare a 0.3 μg/μl solution. Each mRNA was micro-injected into Xenopus laevis Oocytes, (70 nl/Oocyte). Twenty Oocytes in each case was incubated in modified Barth's medium (10 μl/Oocyte) at 20°C for 30 hrs. and the supernatant was recovered to examine lymphocyte activation. As a result, two pools, #6 and 15 showed biological activity. E. Coli HB101 was transformed with the plasmid prepared from pool #6. Three hundred transformants were selected randomly, to prepare thirty new pools. The same screening was repeated for the new pools and five pools showed the activity again. Independent twenty clones were selected from two positive pools and the screening was repeated. Finally, single clones pSP(6-127) and pSP(6-230) were confirmed to yield IL4 activity. The nucleotide sequence was determined by the di-deoxy chain-termination method in both cases. As the result, two clones were obtained carrying essentially the same cDNA. The nucleotide sequence and the deduced amino acid sequence is shown in Figure 1.

Example 2

Construction of the expression vector for human IL4

Plasmid pSP(6-127) was digested with BamHI to excise a 0.8 Kb fragment which contained the whole sequence of human IL4. After treatment with Klenow fragment and HindIII linker attachment, the DNA was inserted into HindIII site of pKCRH₂ (described in K. O'Hare et al., Proc. Natl. Acad. Sci. USA, 78, 1527-1531, 1981) to prepare plasmid pKCRhIL4 (see Figure 2).

Plasmid pSV2neo (described in R. C. Mulligan et al., Science, 209, 1422-1427, 1980) which can express the neomycin resistance gene neo in mammalian cells, was digested with AccI and EcoRI to prepare a 2.5 Kb fragment, which carried neo gene. The excised neo gene was treated with Klenow fragment and a BamHI linker attached. The DNA was then inserted in the BamHI site of plasmid pMDO which can express dihydrofolate reductase (described in S. K. Kim et al., Cell, 42, 129-138, 1985) to prepare plasmid pDneo (see Figure 2). In this plasmid, DHFR and neo are arranged in the same direction. pDneo was digested with EcoRI, treated with Klenow fragment and then a SalI linker attached . Upon digestion with SalI, a 6.5 Kb fragment purified was inserted into the SalI site of plasmid pKCRhIL4 to obtain the expression vector pKCRhIL4-Dn (see Figure 2).

Example 3

Construction of the expression vector of human IL4, wherein the sequence relating to the instability of mRNA was removed

Plasmid pSP(6-127) was digested with SalI, and then further digested with 0.26 unites of Bal 31 (3.5 μg DNA/40 μl reaction mixture) at 30°C. Nine μl of a sample solution was mixed in 1 μl of 0.2M EGTA throughout the time course(2, 4, 6 and 10 minutes). An aliquot (2 μl) was digested with EcoRI and analyzed by PAGE. DNA of one pool which gave rise to a fragment around 100 bp (4 minutes reaction) was treated with Klenow fragment, ligated with an XhoI linker, recirculized and then incorporated to DH₁ to yield about 2,000 transformants. The plasmids were obtained from 120 independent clones and digested with EcoRI and XhoI to examine for the excision of the 100 bp fragment. Twenty-eight clones were selected and partially sequenced. One of them, plasmid pSP(6-127)Δ carried no 3´-noncoding sequence, whose TGA terminal codon and XhoI linker were directly ligated (see Figure 3). The fact shows that the entire nucleotide sequence downstream from the signal sequence for the termination of translation was removed.

Plasmid pSP(6-127)Δ was digested with BamHI and XhoI to excise a 0.5 Kb fragment. Upon treatment with Klenow fragment and attachment of a HindIII linker, the IL4 coding region was inserted into the HindIII

site of plasmid pKCRH$_2$ to obtain plasmid pKCRhIL4∆ (see Figure 3).

Plasmid pMDO described in Example 2 was digested with EcoRI, treated with Klenow fragment, and a Sall linker attached. The 3.5 Kb of Sall fragment which contained DHFR gene was then inserted into the Sall site of plasmid pKCRhIL4∆ to obtain the plasmid pKCRhIL4∆-D (see Figure 3).

5

Example 4

10

Preparation of transformant cells

The plasmid DNA, pKCRhIL4-Dn, was linearized by PvuI digestion. About 1 x 10^6 CHO *dhfr* cells (G.
15 Urlaub et al., Proc. Natl. Acad. Sci. USA, 77, 4216-4220, 1980) in a 10 cm dish were transfected with 20 µg of the linearized DNA by the calcium phosphate co-precipitation method (F.L. Graham et al., Virology, 54, 536-539, 1973).

After 2 days of cultivation in complete medium (αMEM (Flow laboratories) containing 10%(v/v) FBS with hypoxanthine and thymidine), the cells were subcultured in selection medium (αMEM containing 10%(v/v)
20 dialyzed FBS (GIBCO) without hypoxanthine and thymidine) at a split ratio of 1:5.

After 2 weeks of cultivation, a hundred of colonies out of about thousand were isolated and the production level of human IL4 for each clones were measured by growth stimulation of human lymphocytes as described above. The results of 10 representative clones, which were relatively well grown, are shown in Table II below.

25

CHO *dhfr* cells were also transfected with the plasmid DNA, pKCRhIL4∆-D, in the same manner and grown in selection medium for 2 weeks. A hundred colonies were isolated and the production level of human IL4 for each clones was determined. Table III shows the activities of 10 representative clones, which were relatively well grown.

Human IL4 production in the cells transfected with pKCRhIL4Δ-D was about 30 fold higher than that in the cells transfected with pKCRhIL4-Dn.

Two clones (clone No. A-8 and -10) from group A and 6 clones (clone No. B-1, -2, -3, -4, -9 and -10) from group B were selected and about 7×10^5 cells of each clone were placed into a 10 cm disk and cultured in the selection medium containing 50 nM of methotrexate (hereafter "MTX") for 2 to 4 weeks. After the cells were grown to confluence, the IL4 activity in the medium was assayed as described above.

IL4 production in clones A-10 and B-1 was greatly enhanced after MTX treatment. 20 subclones were isolated from these clones.

Enhancement of IL4 production of clone B-9 was not observed by the treatment of 50 nM MTX. Thus, the cells were treated in the presence of 200 nM MTX in the same procedure, and 10 subclones were isolated.

The production of human IL4 in 15 representative clones derived from clones A-10, B-1 and B-9 were shown in Table IV below.

Table IV

MTX resistant clone No.	MTX concentration (nM)	human IL4 activity (units/10^6 cells/day)

B-9-4	"	2800
B-9-5	"	3700

These 15 clones continued to produce IL4 in a high level during the subcultivation periods of 2 months. One of the high producer cell lines, B-9-1, was named as CHO-B91 and has been deposited at the Institute for Fermentation, Osaka, Japan (IFO) with deposit No. IFO 50137 and deposited at the Fermentation Research Institute, Ibaraki, Japan (FRI) with deposit No. BP-1752.

Example 5

Culturing CHO cells transfected by the human IL4 expression vector

Three grams of microcarrier beads (cytodex 3, Pharmacia) were suspended in phosphate buffered saline (pH 7.3) (hereafter "PBS(-)") and autoclaved in a 1 liter scale microcarrier flask (production by Bellco). Then, the PBS(-) was removed and 400 ml of serum free medium (SFM101, Nissui Seiyaku) containing 1%(v/v) fetal bovine serum (FBS), 7×10^7 CHO-B91 cells (prepared in Example 4) was added. The medium were stirred for 2 minutes at 20 r.p.m. and stood for 1 hour in 5% CO_2 in air at 37°C. The cells were attached to microcarrier beads after 4 cycles of this procedure.

Then, 100 ml of SFM 101 medium containing 1%(v/v) FBS were added into the flask and the cells were cultured for 2 days in 5% CO_2 in air at 37°C stirring at 20 r.p.m., 500 ml of the same medium were added and cultured for another 4 days.

The cells were grown in a monolayer on the surface of the microcarrier beads and washed with SFM101 medium to remove FBS.

The cells were maintained for another 24 days by feeding fresh medium and harvesting spent medium every day at 500 ml/day.

Example 6

Purification of human IL4 ·

Twelve liters of the culture supernatants obtained in Example 5 were cooled to 4°C, and acidified by adding 120 ml of 10%(v/v) trifluoroacetic acid (hereafter "TFA"). After adding thereto 120g of Sepralyte C-1 (trade name, prepared by Analytichem International Co.) pre-washed with acetonitrile, the mixture was stirred slowly for two hours. The obtained mixture was allowed to stand for 30 minutes and the supernatants were removed therefrom to recover the beads on glass filter (3G). The recovered beads were washed with a total volume of two liters of 30%(v/v) acetonitrile (containing 0.1%(v/v) TFA) several times at 4°C, and then washed similarly with the total volume of 400 ml of 50%(v/v) acetonitrile (containing 0.1% TFA(v/v)) to wash out the absorbates. The obtained solution was concentrated under reduced pressure below 40°C to remove the acetonitrile, and was absorbed on cation-exchange column (Mono S, trade name, prepared by Pharmacia Co.) pre-equilibrated with 50 mM phosphate buffer (pH 6.0). The column was washed by adding 50 mM phosphate buffer (pH 6.0) for 10 minutes at a flow rate of 2 to 3 ml/min, and then washed by adding 50 mM phosphate buffer (pH 6.0) containing 0.3M sodium chloride until the absorbance (280 μm) become below 0.1. The desired substance was eluted with 50 mM phosphate buffer (pH 6.0) containing 0.4 M sodium chloride as eluent with monitoring by using a Phast System (trade name, prepared by Pharmacia Co.) to collect fractions having a molecular weight of 18 to 20 kd.

The collected fractions were diluted ten times with 50 mM phosphate buffer (pH 6.0) and again absorbed on cation-exchange column. The column was washed by adding 50 mM phosphate buffer (pH 6.0) containing 0.3 M sodium chloride until the absorbance (280 μm) became below 0.02, and then the NaCl concentration was increased lineary from 0.3 M to 0.5 M over 30 min. The fraction was also monitored with UV absorption and sodium dodecylsulfate/polyacrylamide gelelectrophoresis (hereafter "SDS/PAGE").

Ammonium sulfate was dissolved in the collected fractions at a final concentration of 1.7 M and the solution was absorbed on hydrophobic column chromatography (Phenyl•Superose, trade name, prepared by Pharmacia Co.) pre-equilibrated with 50 mM phosphate buffer (pH 6.0) containing 1.7 M ammonium sulfate, and then the concentration of ammonium sulfate was decreased linearly from 1.7 M to 0.0 M over 60 min. with monitoring by UV absorption and SDS/PAGE to collect fractions having a molecular weight of 18 to 20 kd. Mainly broad fractions at 0.5 to 0.3 M were obtained. Next, the fraction having a single band was collected and concentrated by using ultrafiltration (YM-10, trade name, prepared by Amicon Co.) The concentrate was separated by column chromatography with Superose 12 (2.6 x 80 cm) pre-equilibrated with 50 mM phosphate buffer (pH 6.0) to obtain a single broad peak around 0.74 of the column volume. This

was concentrated by using ultrafiltration (YM-10) to obtain the final product.

The concentration of the final product was determined by the color method using bovine serum albumin as a standard (prepared by Biorad Co.). The yields were 5 mg. The recovery indicated by biological activity was 23% of the first culture supernatants.

Example 7

Molecular weight of human IL4

To the pure IL4 (2 μg) obtained in Example 6, the same amount of loading buffer (250 mM tris hydrochloric acid buffer (pH 6.8), 4%(w/v) SDS, 18%(v/v) glycerol, 1.4M 2-mercaptomethanol, 0.01%(w/v) bromophenol blue) was admixed. The mixture was heated for three minutes at 100°C, and then separated by using SDS/PAGE [10 ~ 20%, 1 mm, slubgel, product of Dai-ichi-Kagaku-Yakuhin]. A single band was obserbed by Coomasie Blue staining at 18 kd. This band was reconfirmed by Silver-stain and the purity was measured as over 98% by a densitometric scan (CS-910, Shimazu) (see Figure 4).

Example 8

Analysis of N-terminal amino acid sequence in human IL4

The following single sequence was confirmed by using a liquid phase protein sequencer (Model 477A, prepared by Applied Biosystem Co.):

His-Lys-X-Asp-Ile-Thr-Leu-Gln-Glu-Ile-Ile
-Lys-Thr-Leu-Asn-Ser-Leu-Thr-Glu-Gln-Lys
-Thr-Leu-X-Thr-Glu-Leu

(wherein X corresponds to Cys).

The above N-terminal sequence is completely identical with that of human IL4 obtained by culturing COS-7 cells [see Proc. Natl. Acad. Sci., 83, 5394 (1986)]. The above result shows that the separation of a signal peptide between the 24th amino acid, glycine and the 25th amino acid, histidine, both deduced from cDNA sequence, was carried out completely.

Example 9

Amino acid components in human IL4

100 μg of the sample were dissolved in 6N hydrochloric acid and 4%(w/v) thioglycollic acid and hydrolyzed over 22 hours at 110°C under reduced pressure. The hydrolyzate was analyzed by using an amino acid analyzer (Model 835, prepared by Hitachi Co.). The results are shown in Table V below.

Table V

Amino Acids Analysis		
	calculated	observed
aspartic acid and asparagine	10	10.3
threonine	15	14.5
serine	8	7.5
glutamic acid and glutamine	17	17.0
glycine	3	3.3
alanine	8	8.5
valine	3	3.2
cystein	6	5.3
methionine	1	1.0
isoleucine	6	5.5

tyrosine	2	2.1
phenylalanine	6	6.2
lysine	12	12.4
histidine	5	5.2
arginine	9	9.0
proline	1	1.1
tryptophane	1	0.6
total amino acids	129	

Example 10

Sugar Content of human IL4

The molecular weight of only the protein moiety deduced from the cDNA is 14962. Hence, the difference in molecular weight, i.e. about 3000 (about 17%) is considered to be the molecular weight of the sugar chain.

Example 11

Sugar components of human IL4

(a) neutral sugar

To 30 µg of a sample was added 2N trifluoroacetic acid, and the mixture was heated for 6 hours at 100°C to hydrolyze such. Then, the sample was concentrated under reduced pressure to dryness. The obtained solid was dissolved in distilled water to perform HPLC analysis.

The analysis was carried out by using a TSK-gel sugar AXG column (prepared by Toyo Jozo Co.) in 0.5M borate buffer (pH 8.7). As a result, it was confirmed that the sample comprises mannose, fucose and galactose.

(b) amino sugar

To a sample was added 4N hydrochloric acid and the subsequent procedures were carried out similarly to that above for neutral sugar to obtain the sample for analysis.

HPLC analysis was carried out by using a TSK-gel SCX column (prepared by Toyo Jozo Co.) in 0.16M borate buffer (pH 7.6). As a result, it was confirmed that the sample comprises glucosamine.

(c) sialic acid

To a sample was added 0.01M sulfuric acid, and the mixture was heated for one hour at 80°C to hydrolyze such. Then, the sample was concentrated under reduced pressure to dryness. The obtained solid was dissolved in distilled water to perform HPLC analysis.

The analysis was carried out by using a Gelpak C-620-10 (H⁺ form) column (prepared by Hitachi Co.) in 0.3% phosphoric acid. As a result, it was confirmed that the sample comprises N-acetylneuraminic acid (hereafter "NANA").

Further, the ratios of each of the sugar components is shown in Teble VI below.

Table VI

Mol of sugar components/total mols of sugar	
mannose	3.52
fucose	1.42
galactose	3.01
glucosamine	5.06
NANA	2.06

Example 12

Isolectric point of human IL4

Chromatofocusing using a Mono P column (HR 5/20, prepared by Pharmacia Co.) was performed by using 0.2 mg of a sample.

25 mM triethylamine buffer (pH 11.0) as a starting condition was changed to 1/45 diluted pharmalyte 8-10.3 (pH 8.0, product of Pharmacia). A single peak was eluted at pH 9.96 so that the isoelectric point is about pH 10.

Example 13

Deglycosylation of human IL4

Five μg of a sample (1 mg/ml) were treated at 100°C for 3 minutes with SDS at a final concentration of 0.5%(w/v) and 0.1M 2-mercaptoethanol and then reacted for 16 hours at 37°C together with sodium phosphate buffer (pH 8.6) at a final concentration of 0.2M, 10 mM 1,10-phenanthroline, 1.25%(v/v) Nonidet

14

P-40 (NP-40), 10 units/ml N-glycanase (prepared by Genzyme Co.). An aliquot was separated by SDS/PAGE (20%, 1 mm slubgel). A single band was observed Coomasie blue staining at 15 kd.

While the invention has been described in detail and with reference to specific embodiments thereof, it will be apparent to one skilled in the art that changes and modifications can be made therein without departing from the spirit and scope thereof.

Claims

1. Human interleukin 4 characterized by
   (a) a total molecular weight of 17000 to 19000, and
   (b) a sugar chain molecular weight of 2000 to 4000.
2. The human interleukin 4 according to claim 1, wherein the sugar chain molecular weight is 2500 to 3500.
3. The human interleukin 4 according to claim 1, further characterized by
   (c) an isoelectric point of 8.5 to 10.5.
4. The human interleukin 4 according to claim 1, wherein the isoelectric point is 9.8 to 10.1.
5. The human interleukin 4 according to claim 3, further characterized by
   (d) the sugar chain comprising at least mannose, fucose and galactose as neutral sugars.
6. The human interleukin 4 according to claim 3, further characterized by
   (e) the sugar chain comprising at least glucosamine as an amino sugar.
7. The human interleukin 4 according to claim 3, further characterized by
   (f) the sugar chain comprising at least N-acetylneuraminic acid as a sialic acid.
8. The human interleukin 4 according to claim 3, further characterized by
   (d) the sugar chain comprising at least mannose, fucose and galactose as neutral sugars,
   (e) the sugar chain comprising at least glucosamine as an amino sugar, and
   (f) the sugar chain comprising at least N-acetylneuraminic acid as a sialic acid.
9. The human interleukin 4 according to claim 8, further characterized by
   (g) mannose, fucose, galactose, glucosamine and N-acetylneuraminic acid being contained in amounts of 3.0 to 4.0, 1.0 to 2.0, 2.5 to 3.5, 4.5 to 5.5 and 1.5 to 2.5, mols per total mol of sugar, repectively.
10. Human interleukin 4 produced by using as a host, a transformant which is obtained by transfecting dihydrofolate reductase-defective Chinese hamster ovary cells with an expression vector for human interleukin 4, wherein the expression vector comprises:
    (i) a DNA sequence encoding human interleukin 4 at a position downstream from an SV40 early promoter, and
    (ii) a DNA sequence encoding dihydrofolate reductase at a position downstream from a promoter operating in eukaryotic cells.
11. The human interleukin 4 according to claim 10, wherein in the expression vector for human interleukin 4, at least the human interleukin 4 gene nucleotide sequence for instability is removed.
12. The human interleukin 4 according to claim 10, characterized by
    (a) a total molecular weight of 17000 to 19000, and
    (b) a sugar chain molecular weight of 2000 to 4000.
13. The human interleukin 4 according to claim 12, further characterized by
    (c) an isoelectric point of 8.5 to 10.5.
14. The human interleukin 4 according to claim 13, further characterized by
    (d) the sugar chain comprising at least mannose, fucose and galactose as neutral sugars.
15. The human interleukin 4 according to claim 13, further characterized by
    (e) the sugar chain comprising at least glucosamine as an amino sugar.
16. The human interleukin 4 according to claim 13, further characterized by
    (f) the sugar chain comprising at least N-acetylneuraminic acid as a sialic acid.
17. The human interleukin 4 according to claim 13, further characterized by
    (d) the sugar chain comprising at least mannose, fucose and galactose as neutral sugars,
    (e) the sugar chain comprising at least glucosamine as an amino sugar, and
    (f) the sugar chain comprising at least N-acetylneuraminic acid as a sialic acid.
18. The human interleukin 4 according to claim 17, further characterized by

(g) mannose, fucose, galactose, glucosamine and N-acetylneuraminic acid being contained in amounts of 3.0 to 4.0, 1.0 to 2.0, 2.5 to 3.5, 4.5 to 5.5 and 1.5 to 2.5, mols per total mol of sugar, respectively.

19. An expression vector for human interleukin 4, which comprises:

(i) a DNA sequence encoding human interleukin 4 at a position downstream from an SV40 early promoter and

(ii) a DNA sequence encoding dihydrofolate reductase at a position downstream from a promoter operating in eukaryotic cells.

20. The expression vector according to claim 19, wherein at least the human interleukin 4 gene nucleotide sequence for instability is removed.

21. A transformant which is obtained by transfecting dihydrofolate reductase-defective Chinese hamster ovary cells with an expression vector for human interleukin 4, which comprises:

(i) a DNA sequence encoding human interleukin 4 at a position downstream from an SV40 early promoter and

(ii) a DNA sequence encoding dihydrofolate reductase at a position downstream from a promoter operating in eukaryotic cells.

22. The transformant according to claim 21, wherein in the expression vector for human interleukin 4, at least the human interleukin 4 gene nucleotide sequence for instability is removed.

Claims for the following contracting States: ES, GR

1. A process for the production of human interleukin 4 characterized by
(a) a total molecular weight of 17000 to 19000, and
(b) a sugar chain molecular weight of 2000 to 4000,
which is characterized by culturing a transformant obtained by transfecting dihydrofolate reductase-defective Chinese hamster ovary cells with an expression vector for human interleukin 4 which comprises:

(i) a DNA sequence encoding human interleukin 4 at a position downstream from an SV40 early promoter and

(ii) a DNA sequence encoding dihydrofolate reductase at a position downstream from a promoter operating in eukaryotic cells.
